

## Project Planning Phase

### Project Logic

#### Introduction

The Metro Ticket Generation System is designed to automate the metro ticket booking process using the ServiceNow platform. The project follows a structured workflow that begins with passenger ticket booking and ends with QR-based ticket verification. The entire process is automated using Service Catalog, Catalog Client Scripts, Flow Designer, Business Rules, Notifications, and custom tables.

## **Project Workflow**

The passenger accesses the Metro Ticket Booking catalog item through the Service Portal. The passenger enters the journey details including source station, destination station, journey type, number of passengers, and travel date. Catalog Client Scripts and UI Policies validate the entered information before submission.

After successful validation, the Service Catalog request is submitted, which triggers a Flow Designer workflow. The flow retrieves all catalog variables and creates a new booking record in the Metro Ticket database. Business Rules calculate the fare based on the selected route, generate a unique ticket number, and create a QR value associated with the booking.

Finally, the system stores the ticket details in the database and sends a confirmation notification to the passenger. The generated QR code is used later by ticket inspectors for verification.
